

ROLLING ELEMENT RETAINER

BACKGROUND OF THE INVENTION

Field of the Invention

The present invention relates to a rolling element retainer, and
5 more particularly to a rolling element retainer which is applied to linear
transmission device, wherein the linear transmission is applied to
mechanical, electronic, automatic or semiconductor equipments.

Description of the Prior Arts

Conventional rolling element retainer can generally be divided
10 into two categories: the first type of rolling element retainer is a single
independent unit; the second type of rolling element retainer is comprised
of plural independent units. Referring first to Fig. 11, wherein a slide
block is slidably mounted onto a rail, the slide block is interiorly
provided with rolling elements 30, between the rolling elements 30 is
15 defined with plural single independent retainers 40 for preventing
collisions of the rolling elements 30 with each other. In assembly, it is
very time-consuming for the workers because they have to sequentially
assemble the respective rolling members and the single independent
retainers one by one into the slide block. Furthermore, the single
20 independent retainers need to be tightly contacted the rolling elements,
otherwise, the respective single retainers are susceptible to disengaging
from the rolling elements at both sides, such that the circulation path will
be jammed. But if the contact is too tight, which will lead to a bigger

friction between the retainers and the rolling elements.

Referring again to Fig. 12, which shows a rolling element retainer comprised of plural independent units, wherein the rolling element retainer 41 includes plural partitions 411 which are connected
5 with a flexible chain 412, so as to allow respective rolling elements 30 to rotatably receive in intervals between the respective partitions 411. Such kind of retainer 41 is produced by initially putting the rolling elements into mould, and then processed with plastic ejection molding, however, the requirement on the quality of the plastic material and the performance
10 of the ejection molding machine is very strict, and thus the cost is relatively increased. Furthermore, due to the special manufacturing methods, the contact between the rolling elements and the partitions is kind of tight, which will result in a big rolling friction, accordingly the cornering ability of this kind of rolling element retainer is limited.

15 The present invention has arisen to mitigate and/or obviate the afore-described disadvantages of the conventional rolling element retainer.

SUMMARY OF THE INVENTION

The primary object of the present invention is to provide a
20 rolling element retainer which is possessed with better cornering ability, such that the rolling element retainer is allowed to freely move in a complicated circulation path, and the rolling elements can roll smoothly.

In accordance with one aspect of the present invention there is

provided with a rolling element retainer which having intervals for sequentially receiving plural rolling elements and generally comprising plural partitions serving to separate the rolling elements from each other, each partition provided at both sides with a curved face in corresponding
5 to curvature of the rolling elements; a plural link-rings employed to connect the partitions; each of the partitions and the link-rings is independent unit, the rolling element retainer in accordance with the present invention being comprised of such plural independent units, the engagement between the respective independent units is in a form that a
10 cylindrical ring portion angularly movable engages with a curved surface, by this way, a rolling element retainer with desired length can be formed by alternatively connecting the link-rings and the partitions together, such that the rolling element retainer can be possessed with better cornering ability in universal direction.

15 The present invention will become more obvious from the following description when taken in connection with the accompanying drawings, which shows, for purpose of illustrations only, the preferred embodiment in accordance with the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

15 **DETAILED DESCRIPTION OF THE PREFERRED**
EMBODIMENTS

Referring to Fig. 1, wherein a rolling element retainer is shown and generally comprised of partitions 20 and link-rings 10. The partitions 20 serve to separate rolling elements (not shown) from each other so as to
20 reduce frictions, whereas the link-rings 10 are employed to connect the partitions 20. In assembly, an end of the link-ring 10 is fixed to a partition 20 and another end of the link-ring 10 is connected to another partition 20, such that a retainer with a certain length can be formed by

connecting the link-rings 10 with the partitions 20 alternatively together.

Referring to Figs. 2-4, wherein the partition 20 is provided at both sides thereof with a curved face 21 respectively in corresponds to the curvature of the rolling element (not shown). One side of the partition
5 20 is provided with a trough 22 having curved bottom, whereas opposite side of the partition 20 is defined with a groove 23, such that the partition 20 can be connected to the link-ring 10 of Fig. 1 and forms a rolling element retainer. In addition, since the trough 22 of the partition 20 is designed as having curved bottom, which allows relative angular
10 movement in left-to-right direction between the partition 20 and the link-ring 10.

Referring to Fig. 5, wherein the connecting 10 is shaped as an incomplete ring, which has a first open end provided with two fixing ends 11 for engaging the groove 23 of the partition 20, and also has a
15 second end provided with slight cylindrical-shaped ring portion 12 for engaging the trough 22 of the partition 20 as shown in Fig. 2. By such arrangements, a rolling element retainer can be formed by connecting plural link-rings 10 with plural partitions 20. Since the ring portion 12 of the link-ring 10 is slightly cylindrical shaped, which allows relative
20 angular movement in vertical direction between the partition 20 and the link-ring 10.

Referring to Figs. 6-8, which shows a rolling element retainer in accordance with another embodiment of the present invention, wherein

the rolling element retainer generally comprises partitions 20A and link-rings 10A, the greatest distinction of this rolling element retainer over that of the prior embodiment in this case is that the ring 10A is complete-ring shaped as having ring portions 11A defined at its both sides.

5 Whereas on both sides of the partition 20A is provided an trough 22A having a curved bottom, in this way, a rolling element retainer can be formed by engaging the ring portions 11A of plural link-rings 10A respectively in the troughs 22A of plural partitions 20A. The structure of this kind of rolling element retainer is relative simpler and has symmetry,
10 the ejection molding of which is relatively easier, thereby the production cost can be accordingly reduced. Furthermore, this rolling element retainer is easy to be assembled.

Fig. 9 shows a rolling element retainer being curved like a corkscrew. Fig. 10 shows both ends the curved rolling element retainer in
15 Fig. 9 being connected together to form a ring shape. Wherein rolling elements 30 are confined in the intervals between the respective link-rings 10 and the partitions 20, it can be learned from the drawings that the rolling element retainer of the present invention can be universally turned, which is most applicable to ball screw, linear guideway, linear
20 ball bearing and such kind of linear transmission devices. In particularly, ball screw should be provided with the rolling element retainer which can be freely turned in universal direction. The link-ring and the partition in accordance with the present invention can be made of wear-resisting

flexible material, so as to improve the cornering ability and prolong the service life of the rolling element retainer of the present invention.

It is concluded from the above descriptions that the rolling element retainer in accordance with the present invention is possessed
5 with the following advantages:

First, the rolling element retainer in accordance with the present invention is comprised of multiple independent units (each unit includes a link-ring and a partition), and the cornering ability of which is not achieved by deformation of the device but by the relative angular
10 movement between the respective independent units, so as to ensure that the rolling element retainer can slide smoothly along the circulation path of the linear transmission device.

Second, the rolling element retainer in accordance with the present invention is comprised of multiple independent units, the
15 respective units are simple structured as being formed by normal ejection molding, in this case, the production cost of it can be substantially lowered.

Third, the respective units of the rolling element retainer in accordance with the present invention are allowed to move angularly
20 with respective to each other, and the engagement between the ring portion and the trough of the respective units is in form of the engagement of cylindrical ring portion with curved surface. By this way, the universal cornering ability of the rolling element retainer in

accordance with the present invention can be substantially improved, which is able to slide smoothly along the circulation path of the linear transmission device without being warped.

Fourth, the connecting and the partition of the present invention
5 can be made of wear-resisting flexible material, so as to improve the cornering ability and prolong the service life of the rolling element retainer of the present invention.

While we have shown and described various embodiments in accordance with the present invention, it should be clear to those skilled
10 in the art that further embodiments may be made without departing from the scope of the present invention.
